1. Problem

Using the data provided in regression.csv estimate a linear regression of y on x1 and x2. Answer the following questions.

- (a) Proportion of variance explained (in percent):
- (b) F-statistic:
- (c) Characterize in your own words how the response y depends on the regressors x1 and x2.
- (d) Upload the R script you used to analyze the data.

Solution

The presented results describe a semi-logarithmic regression.

Call:

```
lm(formula = log(y) \sim x1 + x2, data = d)
```

Residuals:

```
Min 1Q Median 3Q Max -2.68802 -0.67816 -0.01803 0.68866 2.35064
```

Coefficients:

```
Residual standard error: 1.052 on 58 degrees of freedom
Multiple R-squared: 0.6511, Adjusted R-squared: 0.6391
```

F-statistic: 54.12 on 2 and 58 DF, $\,$ p-value: 5.472e-14

The mean of the response y increases with increasing x1. If x1 increases by 1 unit then a change of y by about 296.94 percent can be expected. Also, the effect of x1 is significant at the 5 percent level.

Variable x2 has no significant influence on the response at 5 percent level.

The R-squared is 0.6511 and thus 65.11 percent of the variance of the response is explained by the regression.

The F-statistic is 54.12.

- (a) Proportion of variance explained: 65.11 percent.
- (b) F-statistic: 54.12.
- (c) Characterization: semi-logarithmic.
- (d) R code.
